BACKFLOW PREVENTOR WITH ADJUSTABLE OUTFLOW DIRECTION

ABSTRACT OF THE DISCLOSURE

SA  
5 A backflow preventor which permits adjustment of the  
outflow direction is provided. A conduit provides fluid  
communication between the two valves of the backflow preventor.  
The conduit can be separated, e.g., by cutting along a groove,  
leaving annular flat regions. The annular flats are configured  
10 to engage with a coupler to provide leak-free connection  
between the separated portions of the conduit. The separated  
portions of the conduit can be rotated to adjust the outflow  
direction. Preferably, an infinite number of outflow  
directions are possible, all of which lie in a plane parallel  
15 to the inflow direction.
